In the genesis of depression the brain-pituitary-adrenal system (HPA) and the brain-immune system (HIA) are involved. The aim of this study was to test the hypothesis of a relationship between a chronically activated HIA and a hypersecretion of the adrenocorticotropic hormone (ACTH). The HIA system, as well as the HPA system, is modulated by the sympathetic nervous system (SNS). A chronic stress of the SNS provokes a temporary or permanent activity of this system. Chronic activation of the SNS can lead to a permanent and/or short-term hypersecretion of ACTH and glucocorticoids, which in turn causes, apart from depression, metabolic alterations and dysregulation of the immune system, with enhanced production of cytokines. The correlation of depression with activation of HIA and HPA is not yet clear. Clinical studies did not find any differences in the concentration of ACTH, cortisol, adrenocorticotropin-releasing hormone (ACTH-rP), substance P, the SNS hormones nor in peripheral blood catecholamines between patients with depression and healthy controls. However, it is to be pointed out that depression is associated with a short-term hypersecretion of the catecholamines and SNS hormones, as well as with an acute stress response. Furthermore, depression seems to be related to a subnormal release of the neurotrophins (nerve growth factor (NGF) and brain derived neurotrophic factor (BDNF)). The link between depression, HIA and HPA was already described over a century ago. However, we now face a new therapeutic challenge for depression.The present invention relates to an a1d647c40b
