What do you think? Is it acceptable to use the term "effective pitch" to describe the perceived frequency of a sound? A: There are many ways in which pitch is affected by the vibrating system - including by materials, timbre, geometry, and even the size of the soundhole. You'll find several questions on these sorts of issues here, at least for piano. If you're really interested, there are at least two books, which I've read, that explore the topic in depth. The first is an article in the Journal of the Acoustical Society of America by the late Bary Constantinescu (University of California-Berkeley): The second is a book by University of Kansas-Kansas City professor Robert Faris, who is an expert in the topic and has also published a lot on it: Faris says that, contrary to the common belief, the use of the term "effective pitch" has been limited to a small number of high-pitch instruments such as saxophones, oboes, and tenor saxophones. A: Sure, it is valid to use the term 'effective pitch'. The idea is that the vibration of the sound-producing object will affect the pitch. In fact, the speed of the vibration affects the pitch. The vibration frequency, and the size/shape of the sound-producing object may be used to change the 'effective pitch'. As for the overall pitch, it is true that the 'effective pitch' is affected by all those things as well. But often, there will be a fairly strong correlation between the pitch and the pitch of the actual note. So, 'effective pitch' can be used instead of
